

Address Management Software in PHP

The Arc en Ciel address management software is available in PHP 7.

You have been supplied with 2 program files:-

AddressTest.php
AddressUK_ENC.php

The AddressTest.php file is a short example file that does a simple address lookup on a postcode. This can be modified as you wish.

The AddressUK_ENC.php file contains the address management routines. It is encrypted and therefore cannot be read or modified. The example file contains the line: `include ('AddressUK_ENC.php');` at the head to reference the routines and your code should also include this line.

Both these files should be placed in the document root folder of your web server. With the Apache server this is often: `/usr/local/apache/htdocs`.

You have also been supplied with a folder named AddressData. This contains the data files required by the system. It may be placed at any convenient location. The AddressTest.php test program includes a line giving a suggested location for this folder:-

```
$sDataPath = "c:\\AddressData";
```

This can of course be modified as you wish.

It is now only necessary to start your server and run Internet Explorer or other browser. Point the browser to AddressTest.php and you should see a lookup of a sample postcode.
